Executive Summary

This report provides a comprehensive analysis of the 2025 Seattle U Women's Soccer season, focusing on player load management and its relationship to match outcomes. Key findings include:

- **Efficiency Gap:** Individual players in each position have vastly different weekly high-intensity outputs (times they reach >60% their top speed), suggesting need for individualized efficiency tracking.
- **Accounting for Travel Load:** Back-to-Back away games were more likely to end in a tie or loss. MD-2 sessions should be shorter with high-intensity as the focus to offset travel fatigue. If extra travel days are not permitted, have an activation session as soon as possible.
- **Intensity Density as a Win Predictor** High-speed events per 1,000 yds remains the primary determinate between wins and non-wins, especially when supported by a successful cycle of MD-2 intensity followed by a MD-1 load reduction.

Athlete names have been anonymized. Positional data is presented at the group level only.

Initial Recommendations

1. **Positional Efficiency Floors:** The lead up to games should include a reduced load but maintain intensity (speed and short bursts > distance). Since Midfielders generally carry the highest load, MD-1 practices should focus on more neural stimulation than actual load. Think technical/tactical and skill based drills.
2. **Accounting for Travel Fatigue:** Back-to-Back away games were more likely to end in a tie or loss. MD-2 sessions should be shorter with high-intensity as the focus to offset travel fatigue.
3. **Individualized Percentage-Based Taper:** Core players have vastly different high intensity densities (high intensity events / load) week to week. Focusing on setting a threshold that triggers an automatic “extended rest protocol” if Match Day densities drop 15% from weekly average.

Load and Intensity Trends of Core Players

Core Players are defined as players who averaged more than 60min per game.

Intensity Build up

Positional Trends

Average Positional Workload & Intensity by Match Outcome

Bars = Avg Load | White Text = Avg High-Intensity Events

Team Strengths

- **Effective Defense:** Core defensive players maintained consistent high-intensity density during matches and routinely played full games. Goalkeepers maintained low goals-against ratios throughout the conference schedule.
- **Explosive Potential:** With optimal tapering, the team consistently contributed high-intensity events during matches. The team achieves high intensity density (high-speed events per 1,000 yards), which correlates with winning outcomes.
- **Intelligent Substitutions:** Substituted players (10–60m) contributed significantly to match load and high-intensity events, indicating effective use of the bench to maintain performance levels during demanding travel windows.

Areas of Improvement and Final Recommendations

- **Tapering Consistency:** A portion of match weeks demonstrated sub-optimal tapering patterns, particularly insufficient reductions in load from MD-2 to MD-1. These instances were associated with a ~31% reduction in match-day high-intensity events, suggesting that inadequate tapering may limit the expression of explosive actions during competition. However, variability in match outcomes indicates that tapering alone does not fully explain performance differences.
- **Optimizing MD-2 Load:** MD-2 sessions frequently exhibited high training volumes alongside high-intensity efforts. While this may provide a strong stimulus, excessive volume close to competition may contribute to residual fatigue. Emphasizing high-intensity density (quality) over total volume on MD-2—through targeted explosive and tactical drills may better support match-day readiness without compromising recovery.
- **Recovery:** The short turnaround between conference matches (Thursday–Sunday) represents a critical recovery window. Data trends suggest that players logging >60 minutes on the first match may carry residual fatigue into subsequent fixtures. Structuring Saturday sessions as low-load, tactically focused recovery (e.g., walkthroughs, low-impact movement) may help preserve high-intensity output in the second match and reduce accumulated fatigue. For the Sunday fixture, the ‘Priming’ window is effectively non-existent. The focus must shift entirely from preparation to preservation.

Future monitoring should integrate both load reduction and preservation of high-intensity exposure to ensure players remain primed.

Optimized Conference Week Schedule

Strategic Periodization for Thursday/Sunday Match Cycles

Day	Focus	Goal	Load Strategy
Monday	Active Recovery	Flush fatigue	Low Load. Focus on mobility.
Tuesday	Tactical / MD-2	Nervous System 'Pop'	Intensity Density: Short sprints, 5v5 transitions.
Wednesday	<i>The 15% Taper</i>	<i>Energy Preservation</i>	<i>85% of rolling average. Maintain HI Density Floor.</i>
Thursday	MATCH DAY 1	Peak Output	Maximize HI Density. Maintain Efficiency Floor.
Friday	MD+1 Recovery	System Reset	No on-field load for >60m players. Pool/Bike.
Saturday	Recovery Trough	Soreness Management	Technical walk-throughs and light priming.
Sunday	MATCH DAY 2	Secondary Peak	Target 90% of Thursday's HI Density.

Optimized Schedule Sample
